Experiment No.: 7

1. **Title:** Perform DOM traversal and updates; develop a to-do list app with add, edit, and delete features.

2. **Software/Tools Required:** Visual Studio Code (VS Code), web browser, HTML, JavaScript.

3. **Theory:** DOM (Document Object Model) traversal is the process of accessing and moving through HTML elements using JavaScript. Methods such as getElementById(), querySelector(), parentElement, children, and nextElementSibling are used to locate and navigate elements in the DOM. DOM updates allow JavaScript to dynamically change webpage content, attributes, and styles without reloading the page. A **To-Do List application** demonstrates these concepts by allowing users to add new tasks, edit existing tasks, and delete completed or unwanted tasks. JavaScript creates and modifies HTML elements using methods such as createElement(), appendChild(), textContent, and remove(). Event listeners such as click are used to perform actions when the user interacts with buttons. Thus, DOM traversal and updates make the application interactive and dynamic.

Conclusions: The To-Do List application successfully demonstrates the use of **JavaScript DOM traversal and manipulation**. Tasks can be dynamically added, edited, and deleted based on user actions. This experiment provides a basic understanding of how JavaScript interacts with HTML elements and how event handling can be used to create interactive web applications.
